HOW IT WORKS:

The conveyor consists of multiple accumulation zones. Each zone's tread rollers are driven from underneath by the top surface of a drive belt running the length of the conveyor. Pressure rollers located under the belt push upward providing friction between the drive belt and the tread rollers. Each zone includes a pressure roller carriage, roller brake, air bags and pneumatic valve. **ProLogic** zone controllers sense the presence of products in each zone and control the accumulation or release of the product. If downstream zone is full, the pressure roller carriage in preceding zone drops away from the belt and applies roller brake to stop the product. Once downstream zone is empty, pressure roller carriage raises, roller brake drops away and product will continue down the conveyor.
